

Some of the effect we see from the IIR filter design, such as the zeros at 1 or -1 being a small circle of points, instead of being at one location, is an artifact, not of the design process, but of representing these as a polynomial. To demonstrate this, the following MatLab script will create a polynomial with 21 zeros at 1. Then the zplane plot of this shows the location of the roots of the resulting polynomial. Also the roots are computed using roots.

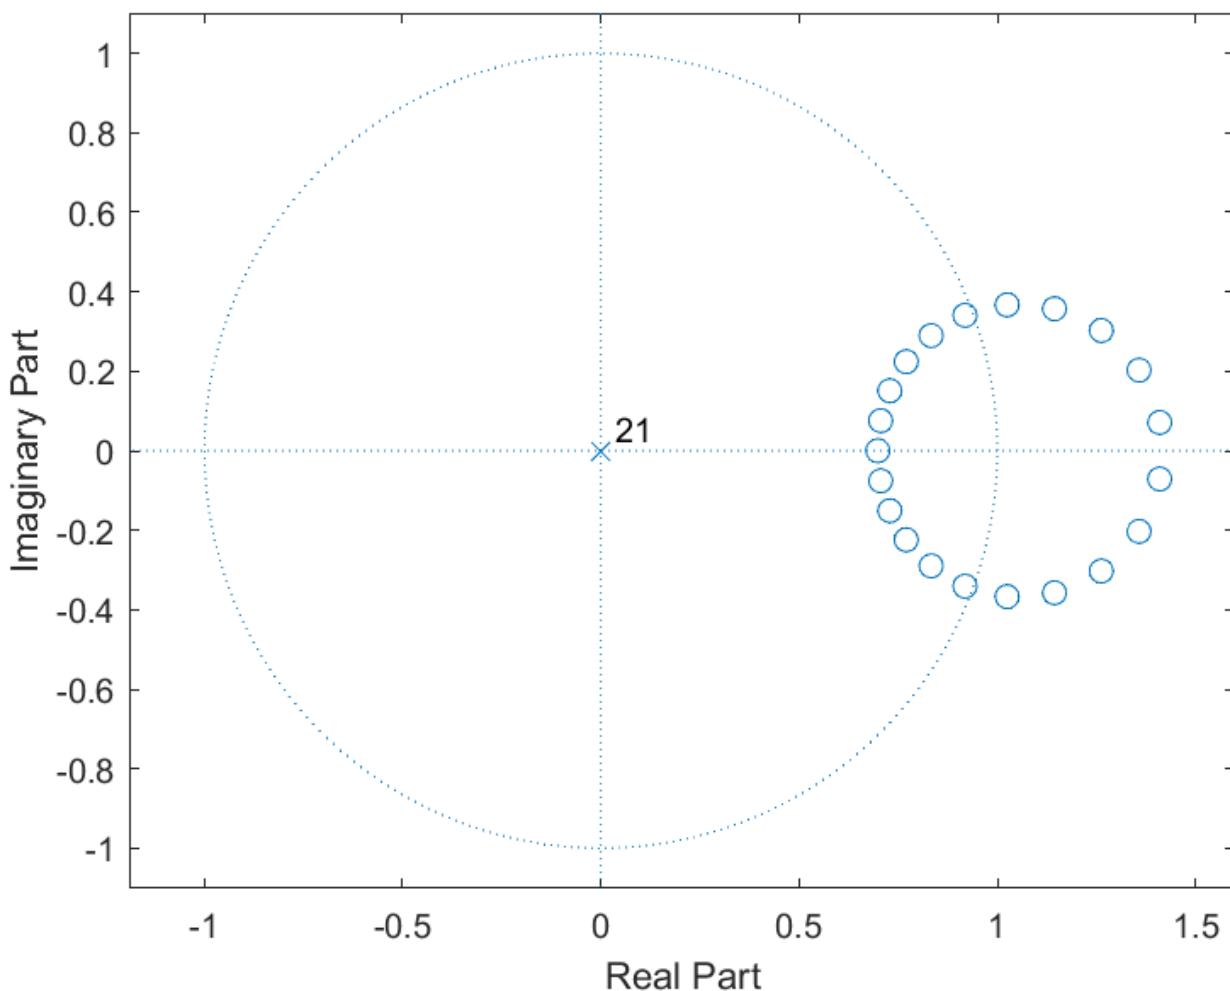

```

z = [1 -1]; % polynomial with root at 1.

z2 = z; % z2 will start as one root at 1.
for k = 1:20 % then we multiply the polynomial z2 with z 20 times.
    z2 = conv( z2, z );
end
% Next print out the coefficients of z2, noting that they don't look odd.
z2
%
% z2 =

% we display the roots in a zplane plot.
zplane( z2, 1 )

```

The 21 zeros are in a circle around +1. Caused by the rounding error of going from a large polynomial to roots.

The following script uses the same calls “butter” and “cheby1”, but requests three results which will be returned as a set of poles and zeros and a gain, rather than a polynomial.

Another aspect of the script is that all the filters are converted to Second Order Systems (sos), which is the most common form to implementing the filters.
